Microseismic Monitoring 101

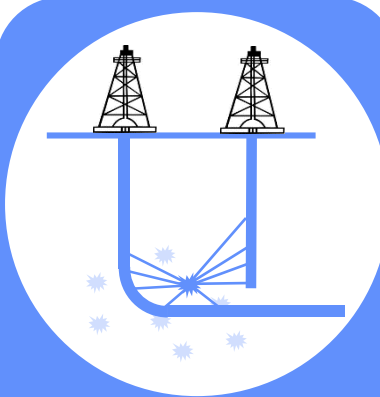

Geometries of acquisition

The diagram shows a single well with a pink casing. A pink starburst source is located at the bottom of the well. Pink lines radiate from the source, representing seismic waves. Small pink starbursts are scattered in the surrounding rock formation. The entire diagram is enclosed in a pink rounded rectangle.

DH - SW

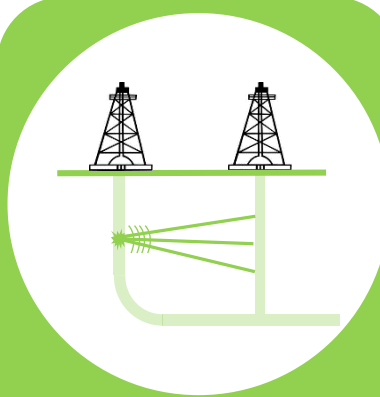

Single well downhole microseismic monitoring using VSI. Superior clamping, quantifiable coupling using proprietary shaker. Decoupled, GAC sensor and leading manufacturing tolerances result in superior signal to noise data.

The diagram shows two wells with blue casings. A blue starburst source is located at the bottom of one well. Blue lines radiate from the source, representing seismic waves. Small blue starbursts are scattered in the surrounding rock formation. The entire diagram is enclosed in a blue rounded rectangle.

DH - MW

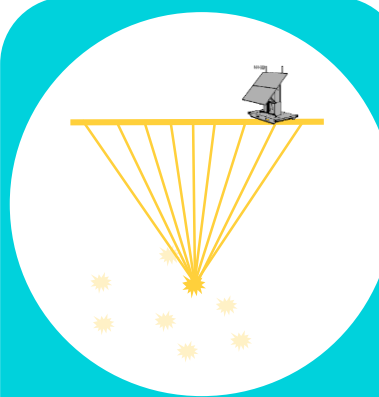

Multi well downhole microseismic monitoring using VSI. Superior clamping, quantifiable coupling using proprietary shaker. Decoupled, GAC sensor and leading manufacturing tolerances result in superior signal to noise data.

The diagram shows two wells with green casings. A green starburst source is located at the bottom of one well. Green lines radiate from the source, representing seismic waves. Small green starbursts are scattered in the surrounding rock formation. The entire diagram is enclosed in a green rounded rectangle.

DLCS

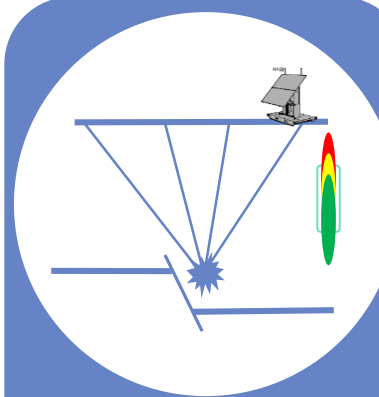

High energy, low impact, downhole source, high frequency imaging, 4D drainage mapper, HFM velocity model calibration. Combinable with VSI & hDVS for complete monitoring and imaging versatility.

The diagram shows a surface well with a yellow casing. A yellow starburst source is located at the bottom of the well. Yellow lines radiate from the source, representing seismic waves. Small yellow starbursts are scattered in the surrounding rock formation. The entire diagram is enclosed in a yellow rounded rectangle.

Surface HFM

Surface microseismic processing of shallow well grid or patch deployment.

The diagram shows a surface well with a blue casing. A blue starburst source is located at the bottom of the well. Blue lines radiate from the source, representing seismic waves. A vertical rainbow-colored bar is shown to the right of the well. The entire diagram is enclosed in a blue rounded rectangle.

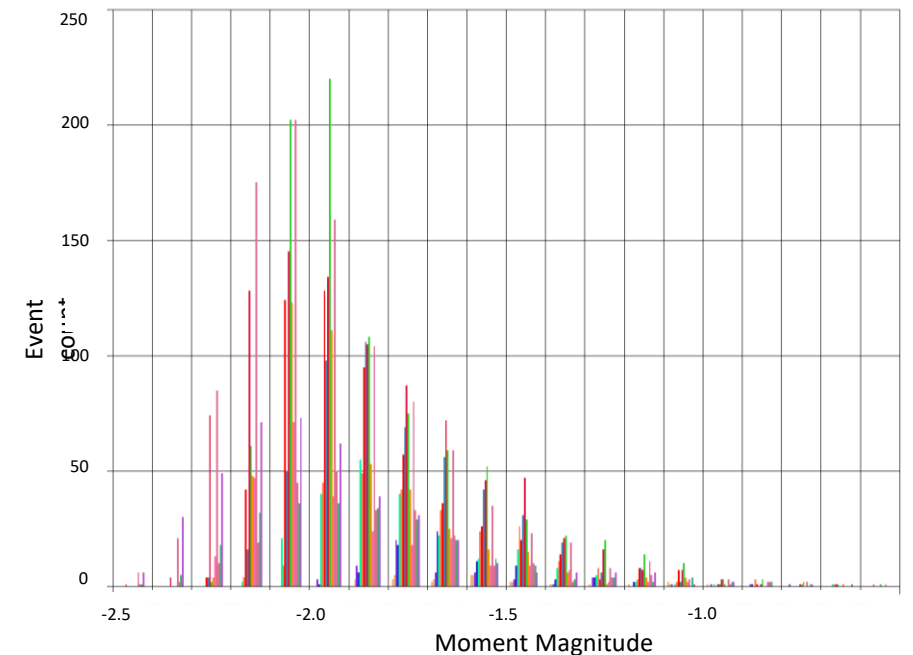

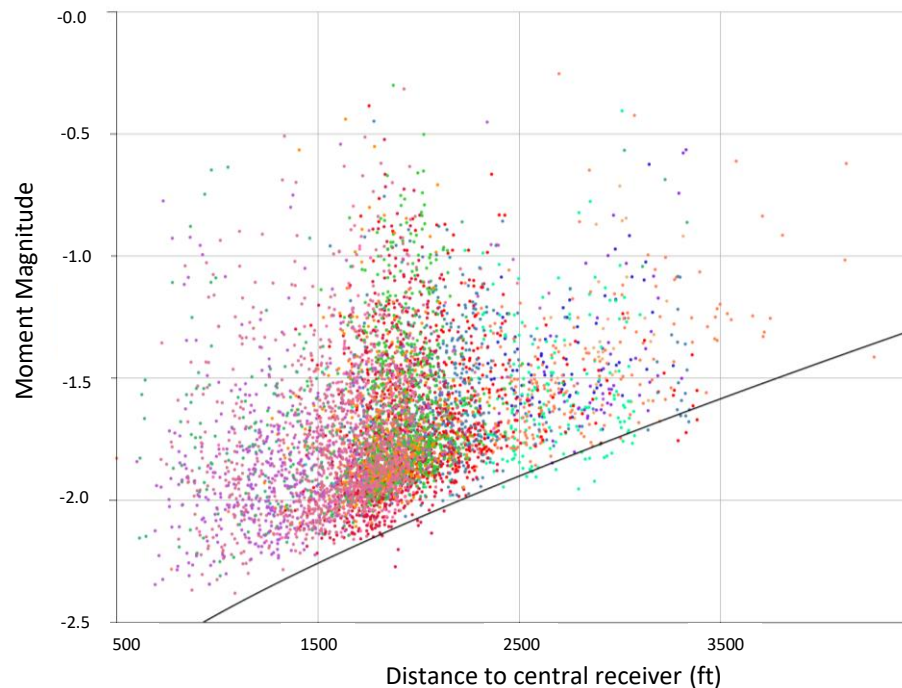

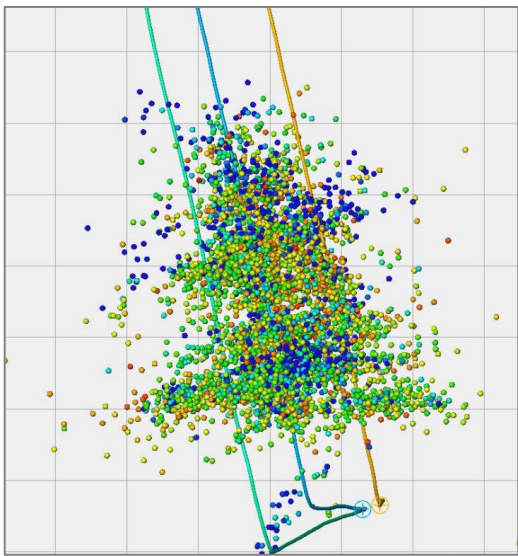

Induced Seismicity Monitoring

Real time surface monitoring of large magnitude events in response to regulatory requirements. Reservoir & monitoring applications including EOR and subsidence.

Microseismic Monitoring 101

Definition of a microseismic event

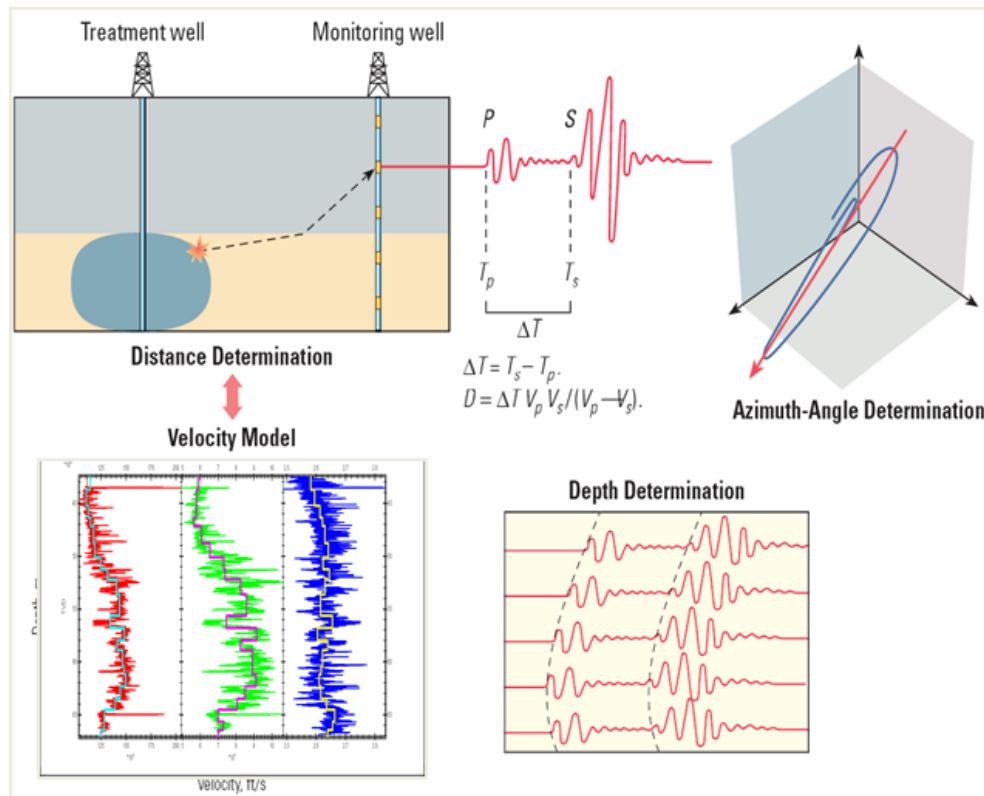

- In principle, **microseismic** describes any events or methods pertaining to *microseisms* — faint earth tremors with natural or human causes. Since about 2000, however, the term has become strongly associated with passive seismic monitoring of production effects, borehole-related phenomena, and especially hydraulic fracture stimulation or *fracking*. (**SEG wiki**) (and geothermal, carbon capture, etc.)
- Microseismic monitoring can tell us when and where a microseismic event occurred and how big it was (measured on the moment magnitude scale).
- Microseismic monitoring can also tell us how the rock failed, what was the mechanism, shear or tensile (i.e. slipping or opening and closing) ?

Microseismic Monitoring 101

Definition of a microseismic event

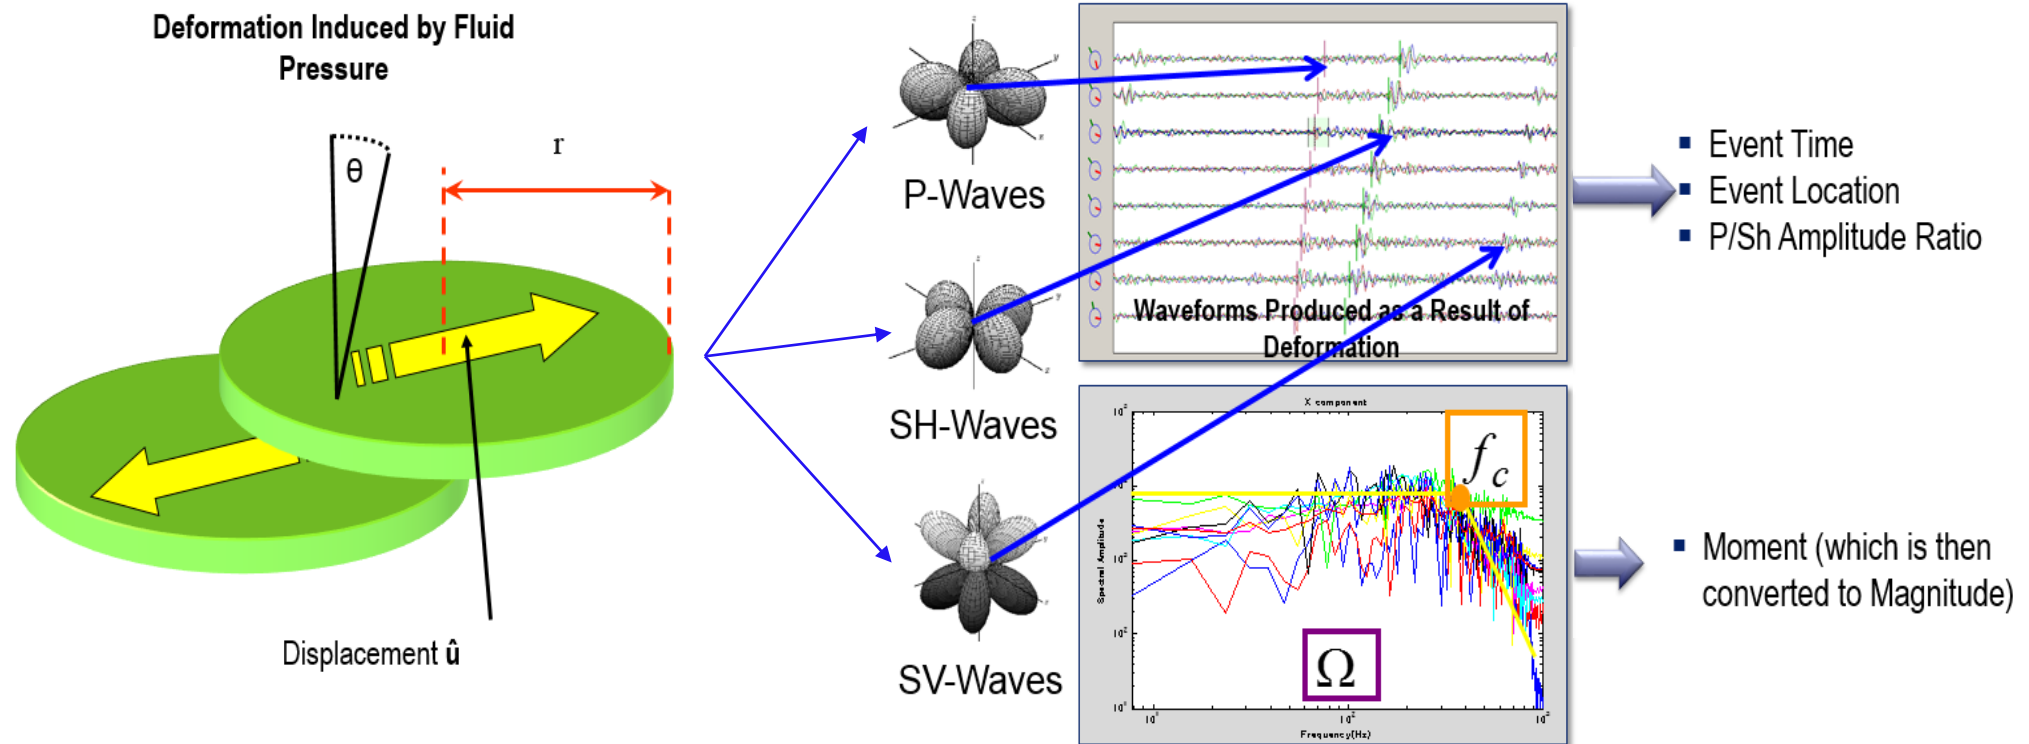

- Rock will deform (crack) when pressure increases beyond its failure criteria
- Energy is released and measured (either downhole or on the surface)
- When (time), where (spatially), and how (mechanism), this occurred can be mapped

Microseismic Monitoring 101

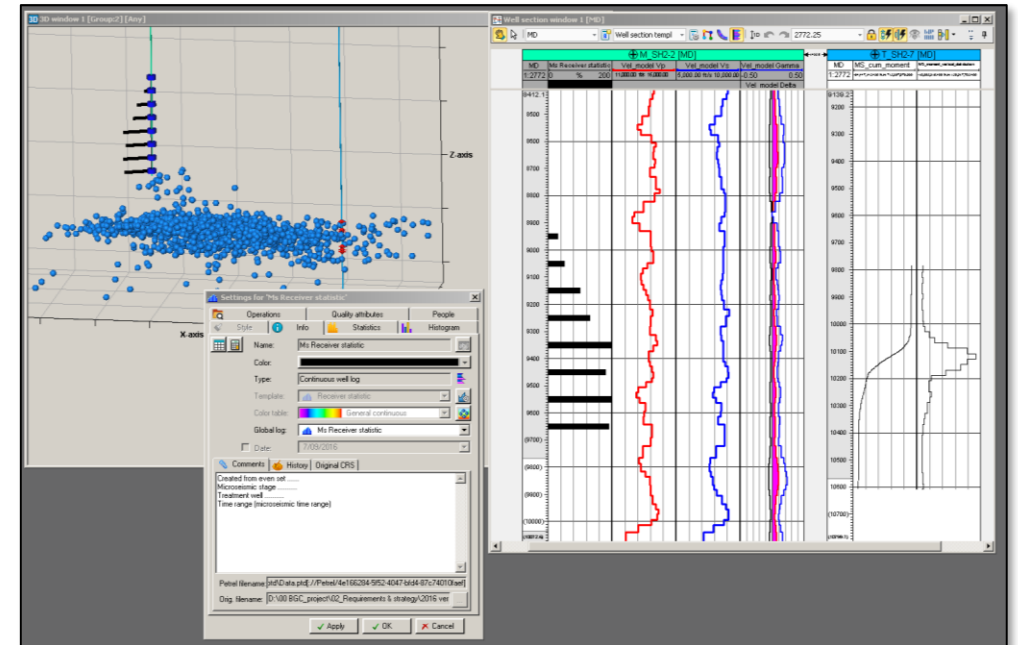

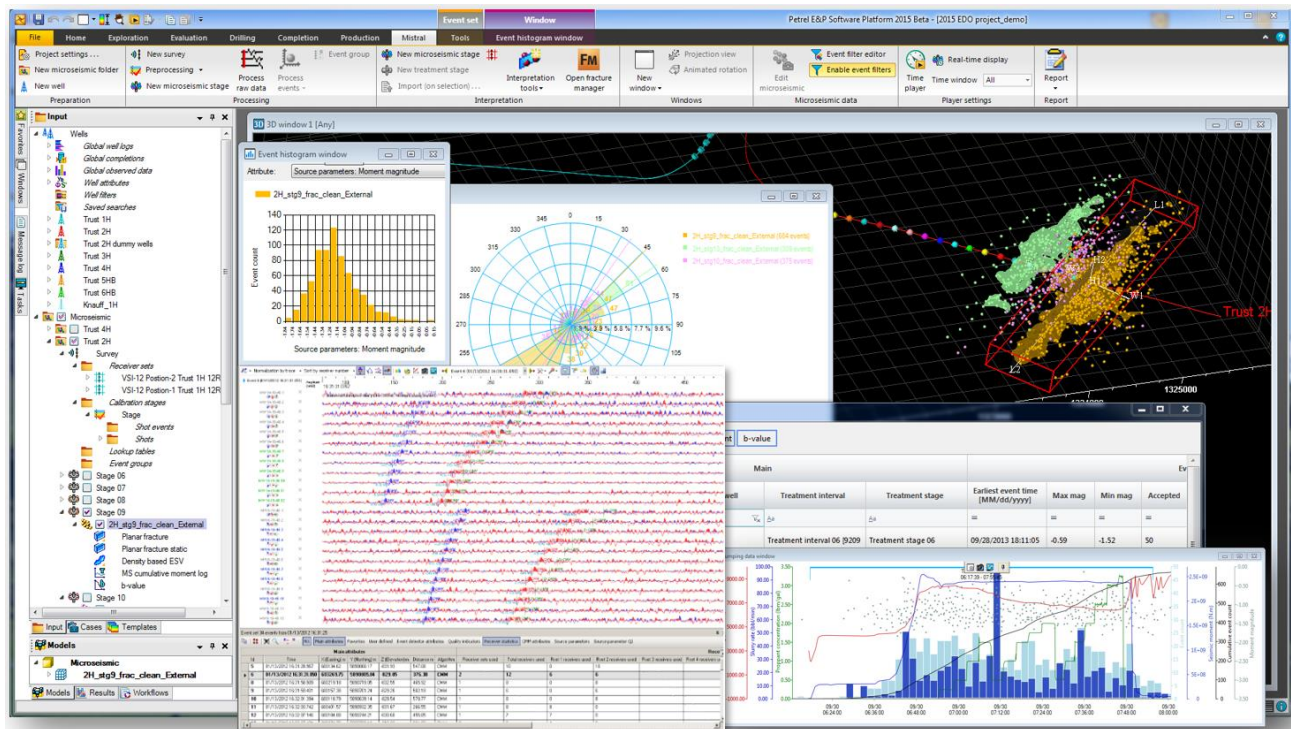

Definition of a microseismic event

- The energy of a microseismic event is expressed as a magnitude similar to the Richter (log) scale used to measure earthquakes
- Microseismic events are typically magnitudes -1 to -4
- An event of magnitude -2 is roughly equivalent to dropping a bag of sugar from the countertop

Microseismic Monitoring 101

How to use a microseismic event

Microseismic Monitoring 101

Requirement for optimal hypocenter mapping

- Optimal placement of geophones
- Accurate wellbore surveys
- Sufficient energy at geophones to generate microseisms
- Accurate estimate of velocity and anisotropy
- Unbiased wideband 3-component sensor response
- Vector fidelity
- Optimal & stable Acoustic Coupling

Which receivers to deploy

Background

Acquisition Simulator

Any substitute for initial testing?

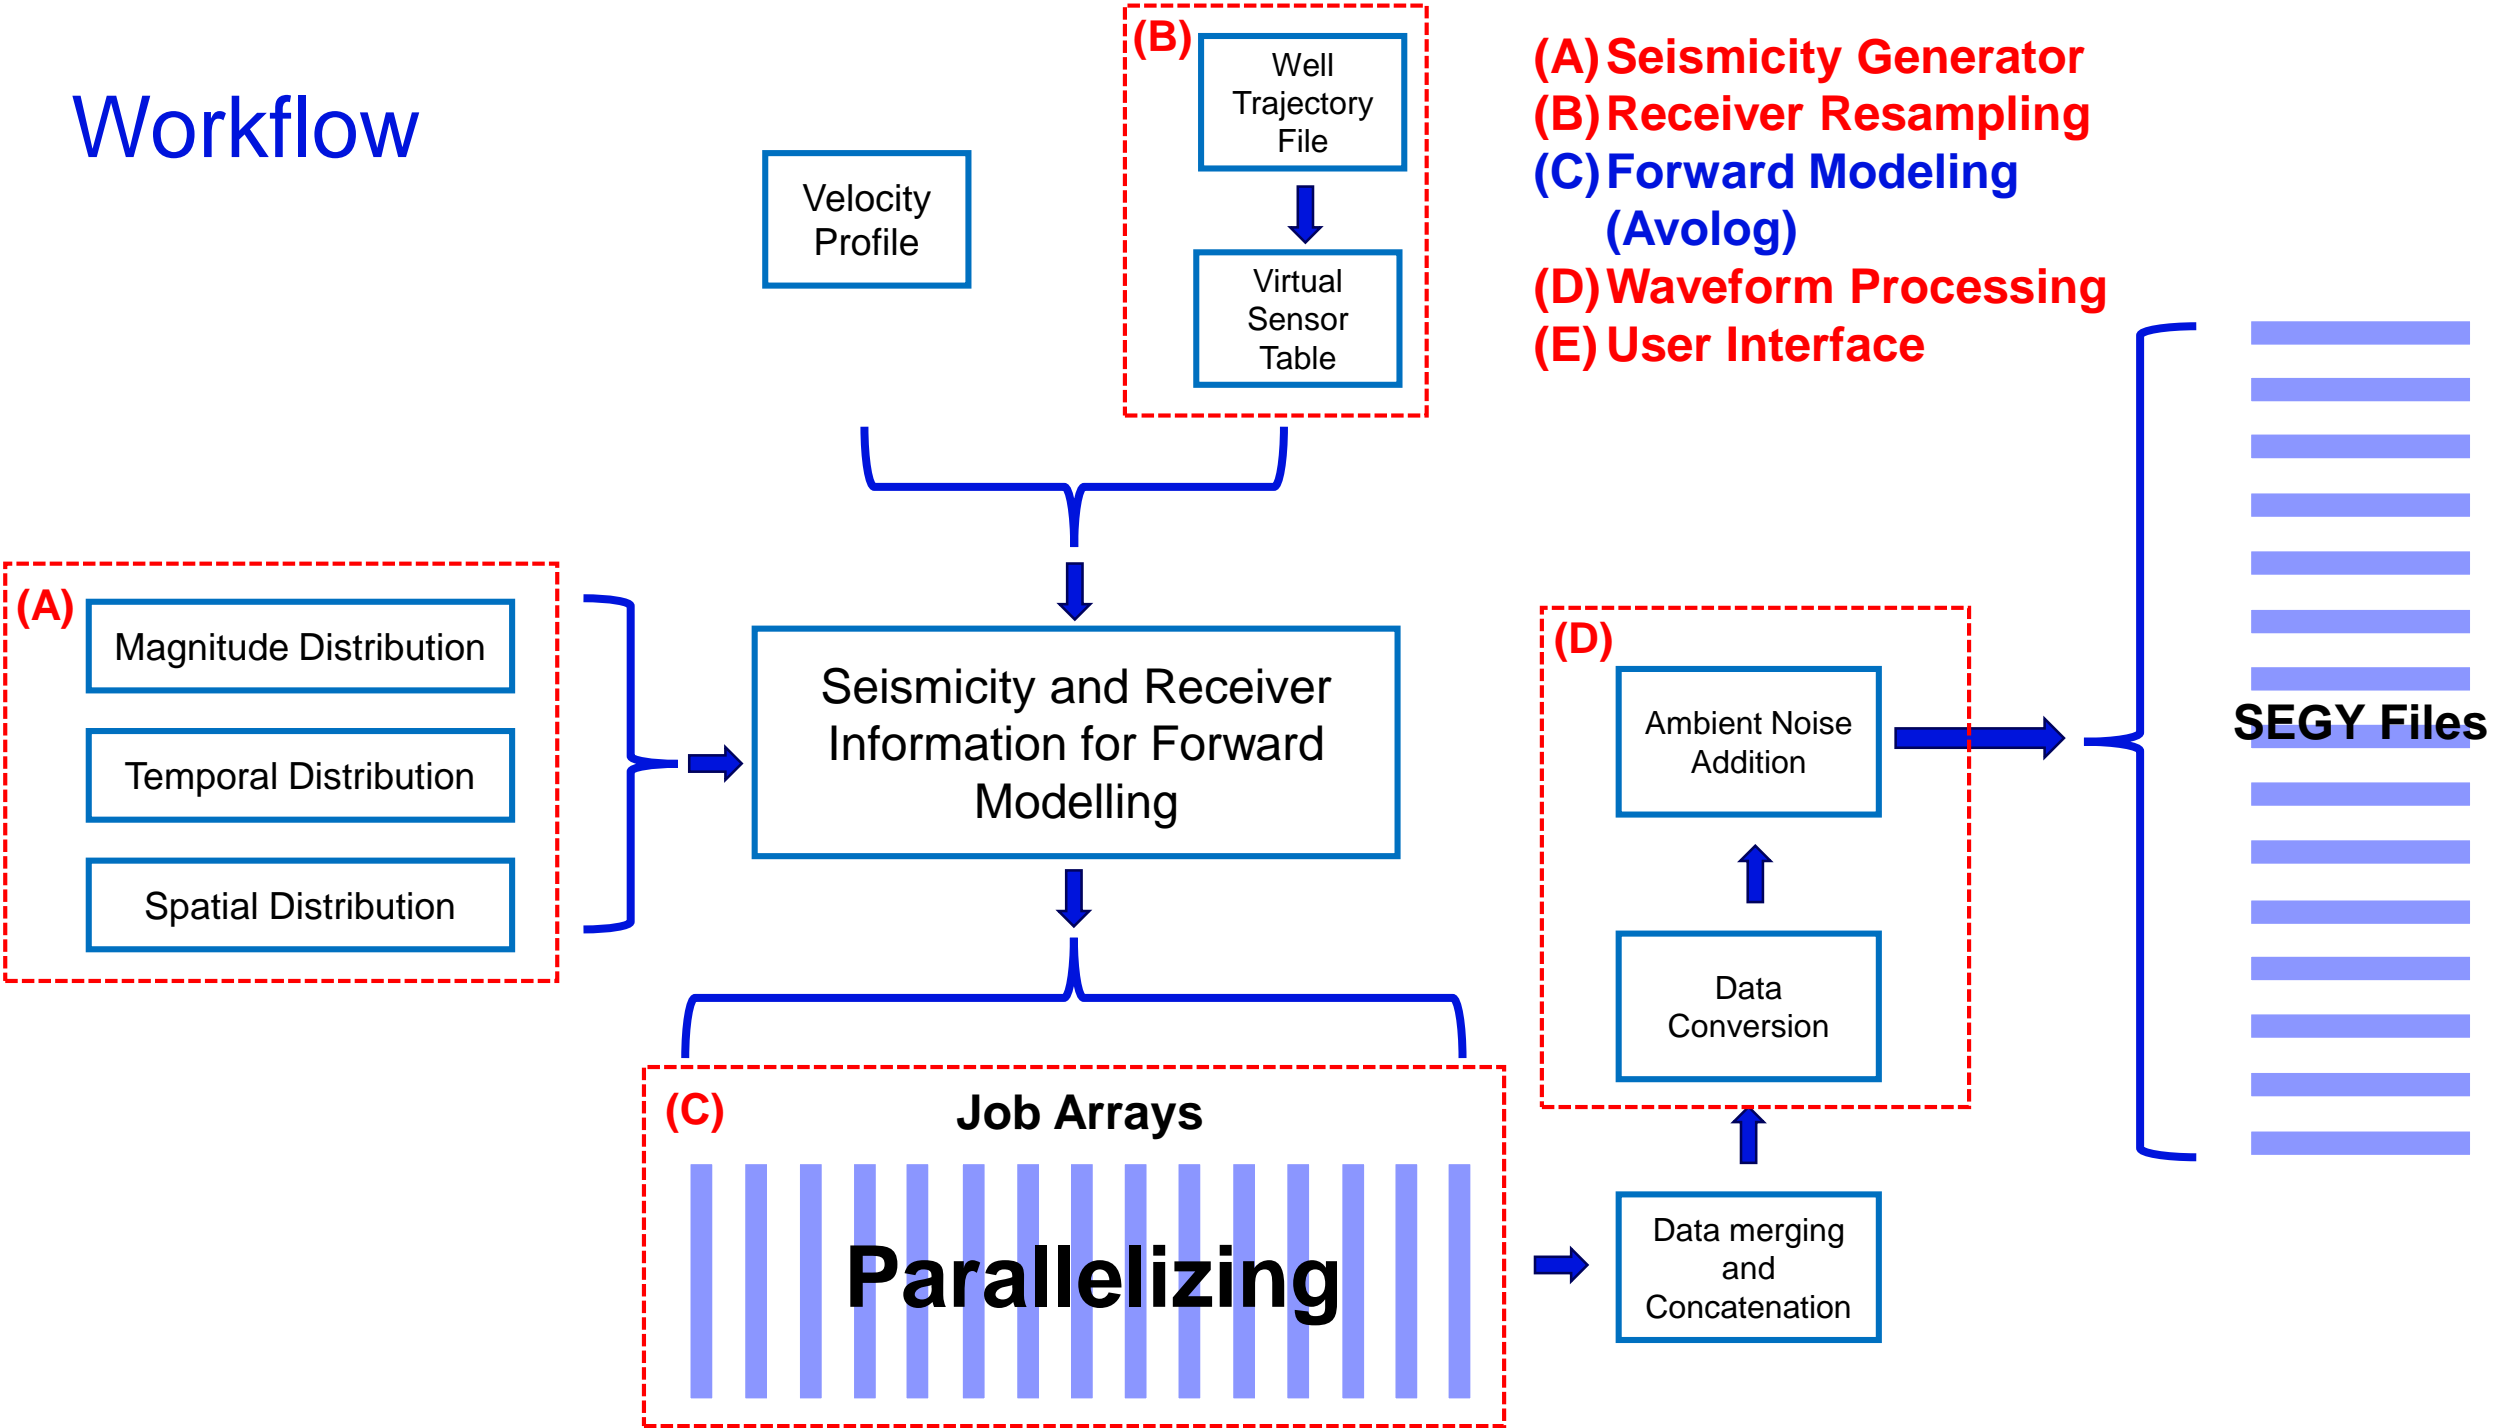

Challenges

- **Seismicity simulation with a scientific rationale**
- **Earthquake waveform modeling and noise modeling**
- **Data format and metadata handling**
- **Capability of simulating data with different settings**
- **Robustness and speed of real-time simulation**

Potential Solutions

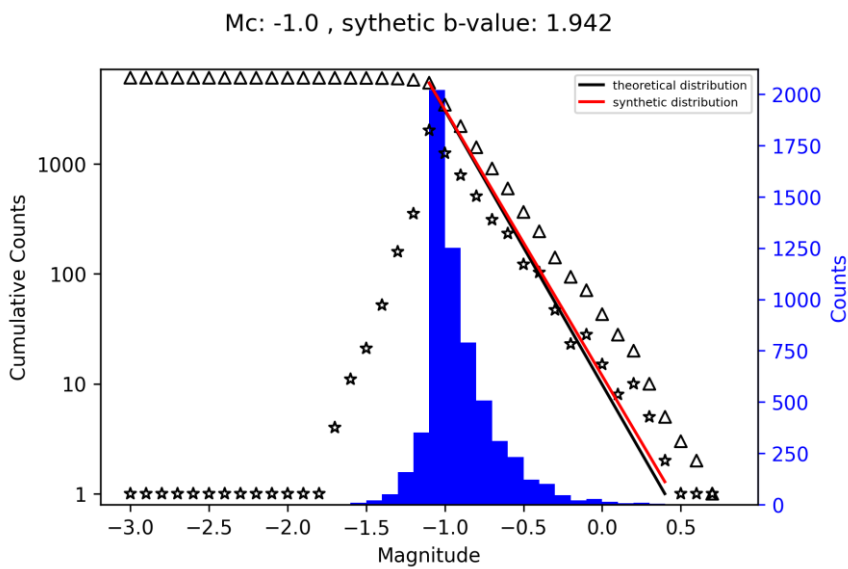

- **Empirical studies**
- **Synthetic generator and data modeling**
- **SEG-Y header handler**
- **Code generalization**
- **Parallelization and testing**

Workflow

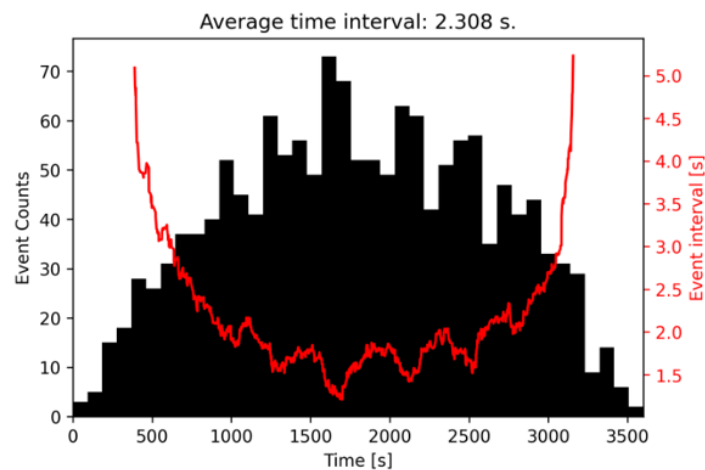

Magnitude distribution: GR-Law

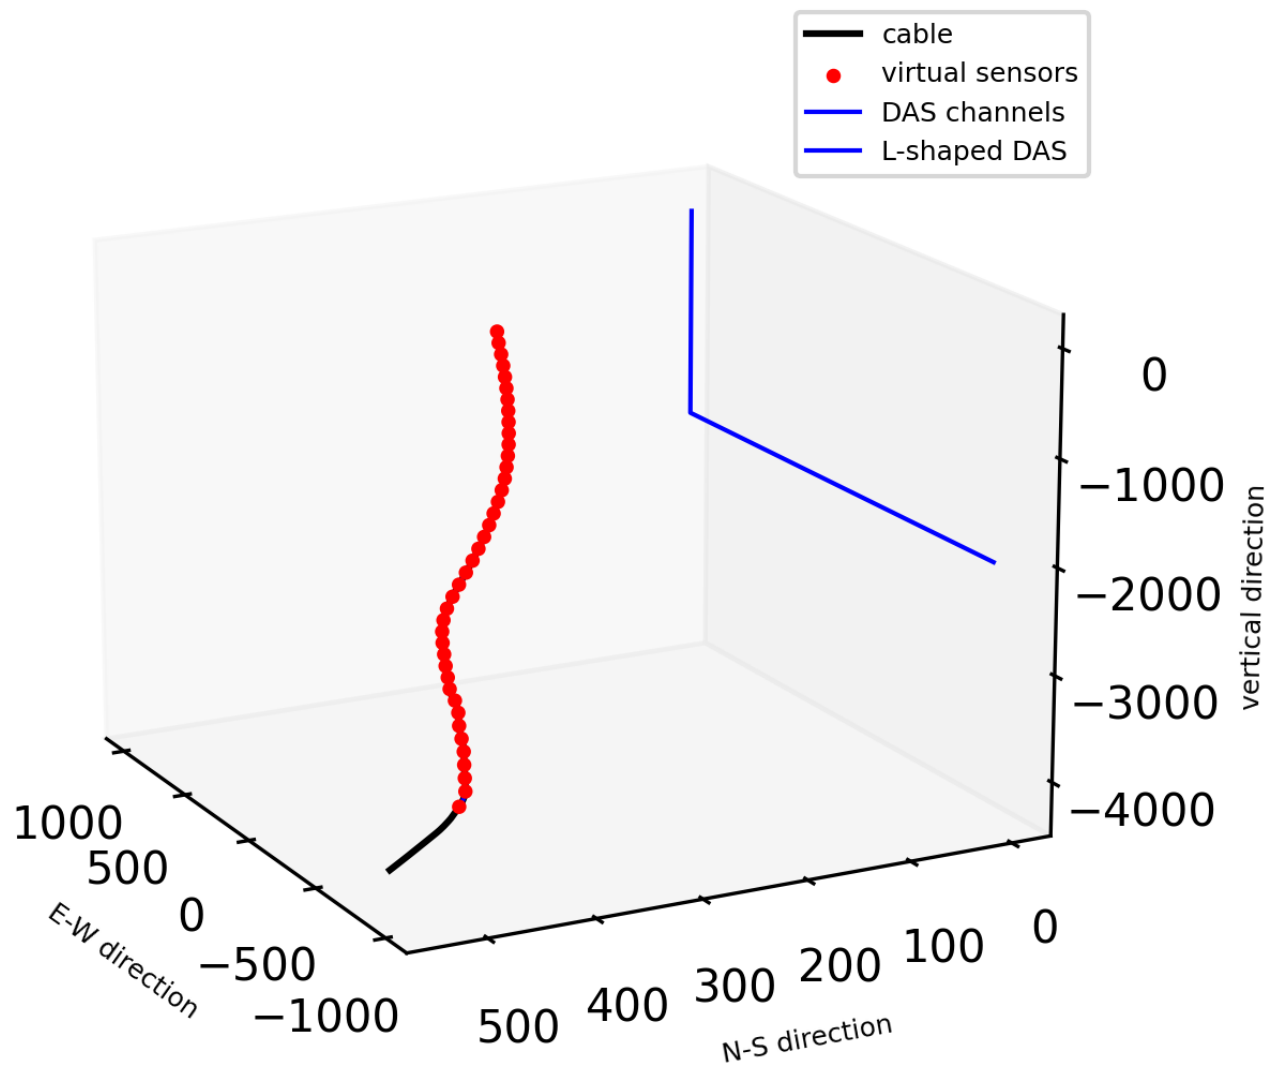

Temporal distribution:
(Non)Homogeneous Poisson

Average time interval: 5.944 s.

Spatial distribution: EQ clusters

- Geophone receiver table (L-shaped well):
 - 2000 DAS channels
- Well trajectory file (smooth well path)
 - 2000 DAS channels
 - Constant spatial interval
 - Spatial integration and resampling

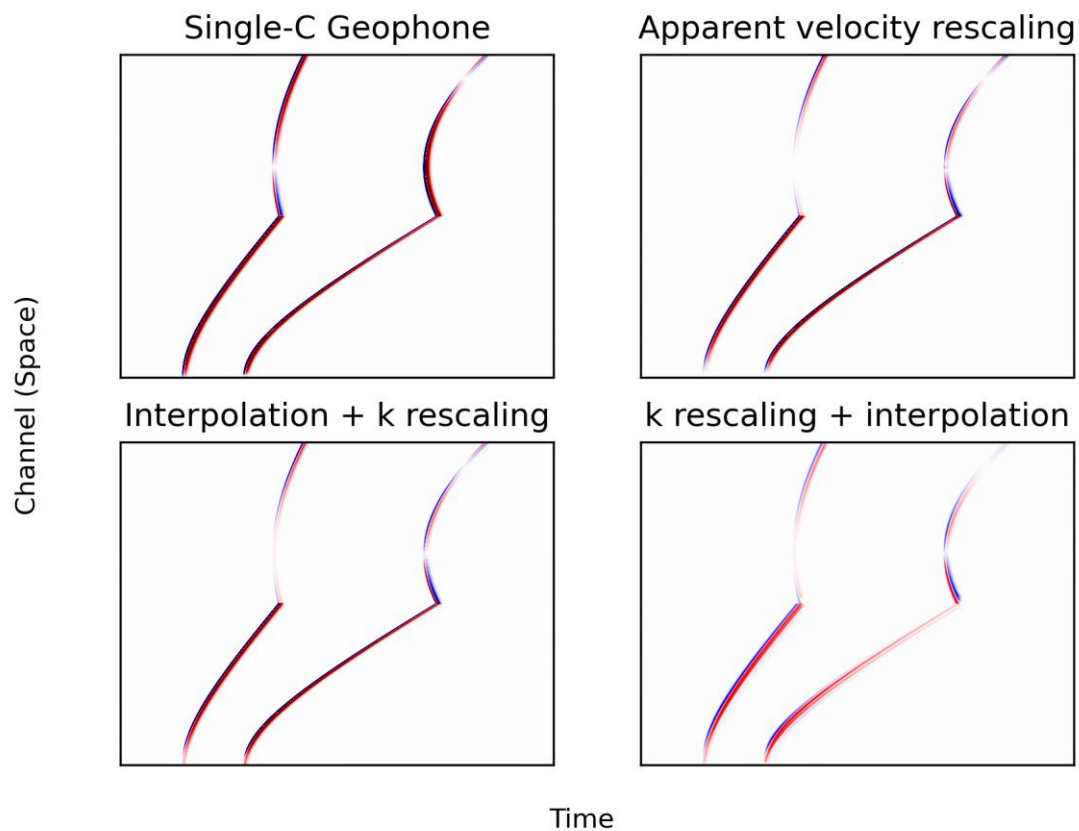

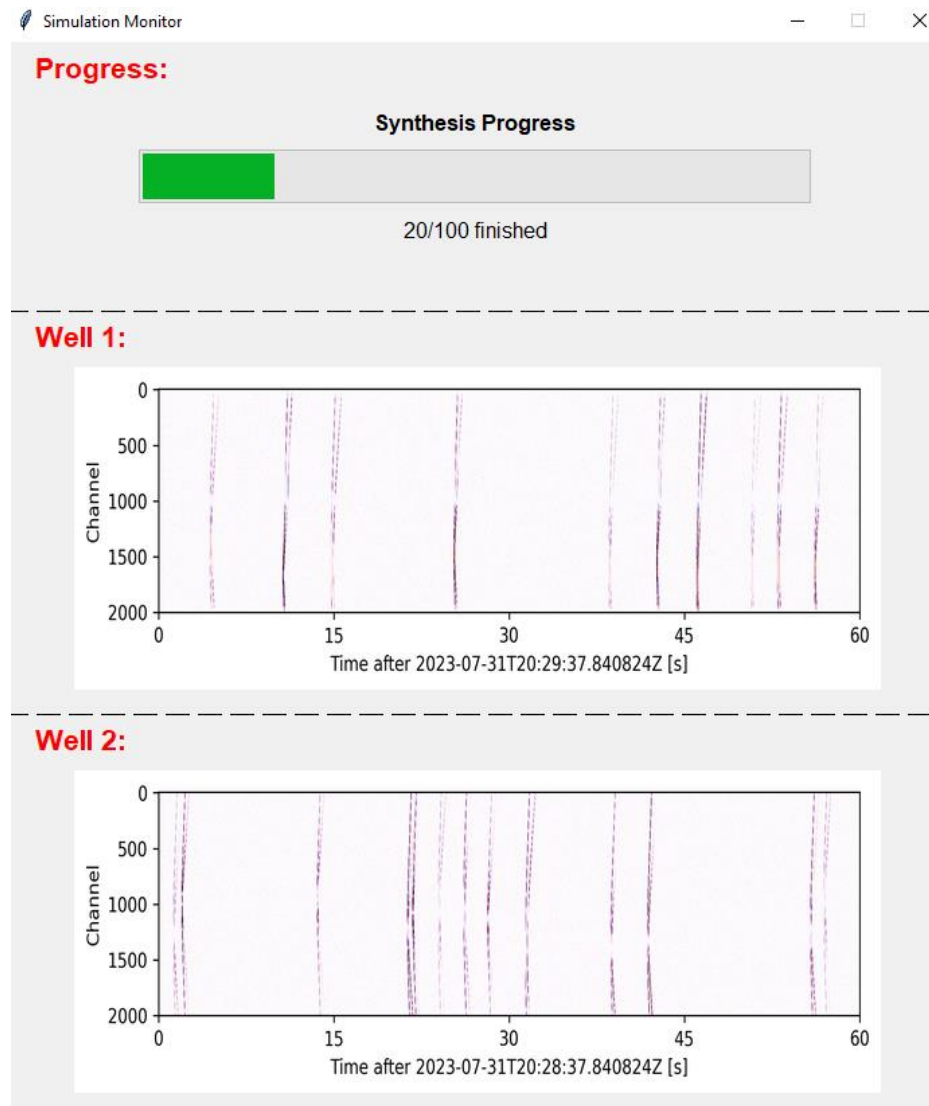

- Forward modeling **with existing tool**
- To achieve real-time simulation scheme:
 - Parallelize waveform modeling with multiple standalone executables
 - Spatial downsampling
 - Interpolation
 - Calculating theoretical arrival time (with homogeneous model) and fine-shifting
- Data concatenation

- Measurement conversion (From velocity /displacement to strain):
 - Apparent velocity rescaling
 - Wavenumber rescaling / ...

- Ambient noise:
 - White noise
 - Modeled noise from borehole data
 - Noise level

- Data output:
 - One-minute batch to optimize memo/CPU usage
 - 6-second files to adapt RTISA
 - Metadata internal handling
 - Progress monitoring and data visualization

Well number	Duration	Seismicity Rate (per minute)	Computation Time	Data Volume
1	1 min	12	24 second	1.35 GB
2	1 min	12	35 second	2.71 GB
2	1 min	20	~ 1 min	2.71 GB
2	1 day	12	~ 13 hour	3.81 TB

Confirm **Run**

Magnitude **Temporal** **Spatial**

Mc: -1.0 , synthetic b-value: 1.942

Well 1 **Well 2**

Real-time scheme

- To achieve real-time simulation scheme, it is not practical to simulate all channels:
 - Parallelize waveform modeling for each earthquake
 - Only sample tens of virtual sensors, the interpolation
 - Calculate theoretical arrival time then fine-shifting
- Data is output every minute, and chunked into 6-second files:
 - Concatenate data of all earthquakes within one minute
 - Figures updating

Testing with RT-ISA

Project Settings

Job file: ...yaolin\slides_for_yaolin\slides_proj.proj

SEG-Y folder: ...\\11\Documents\yaolin\slides_for_yaolin

LDF folder: ...\\11\Documents\yaolin\slides_for_yaolin

Process Parameters

Receiver depth correction: 0

Total receiver number in original SEG-Y: 2000

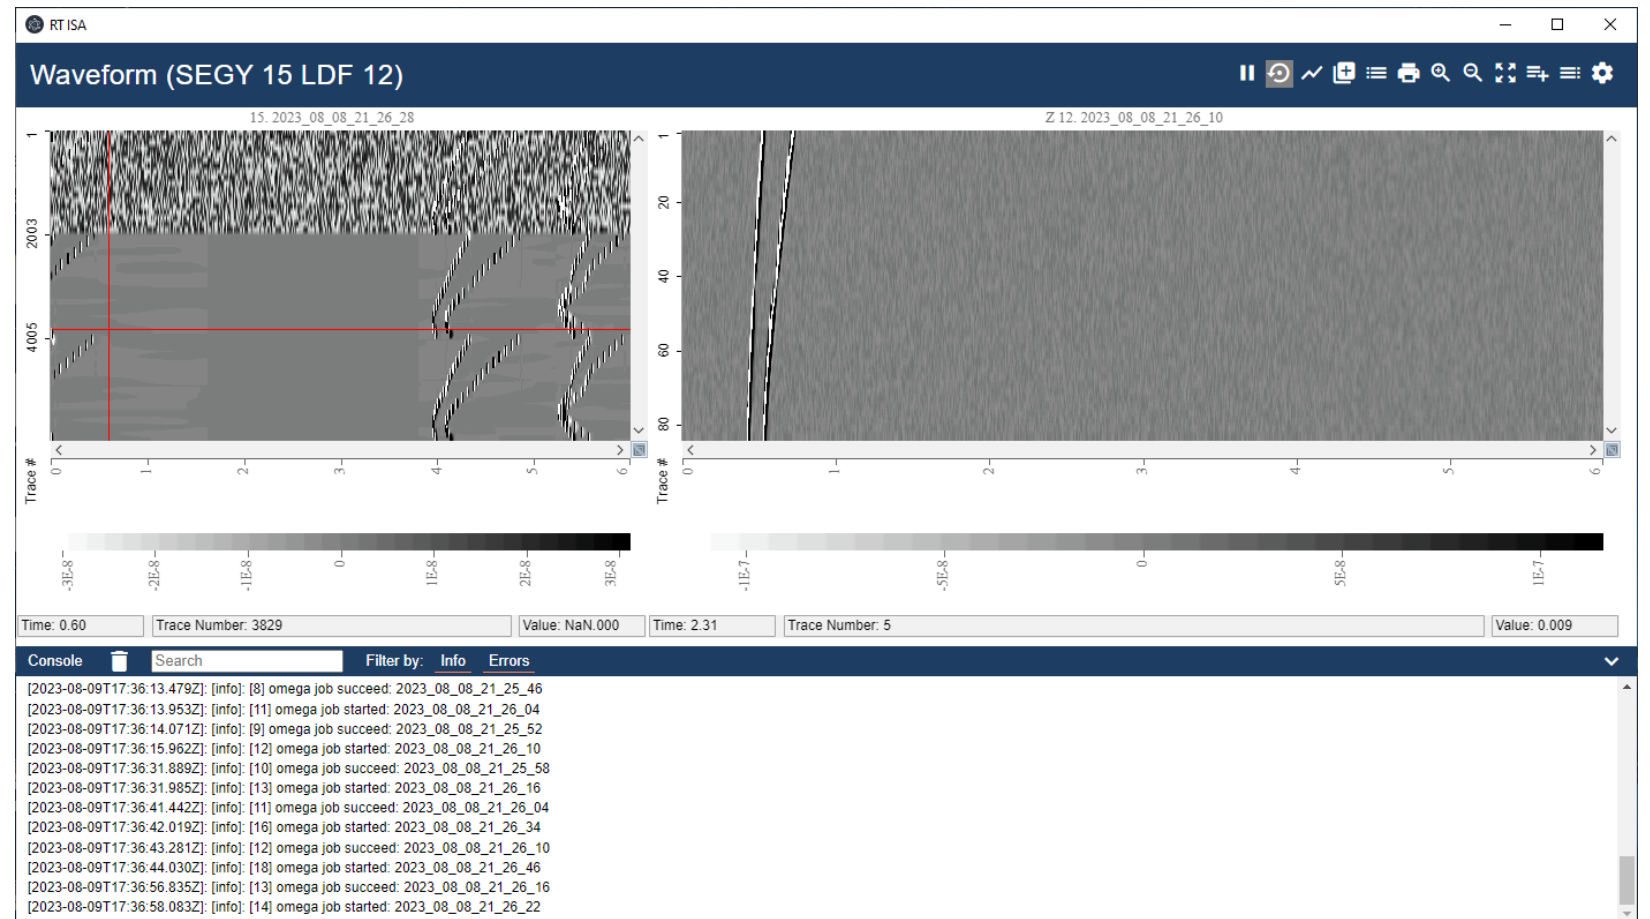

Processing start depth(MD): 1500 (m)

Processing end depth(MD): 2500 (m)

Stacking receiver number: 6

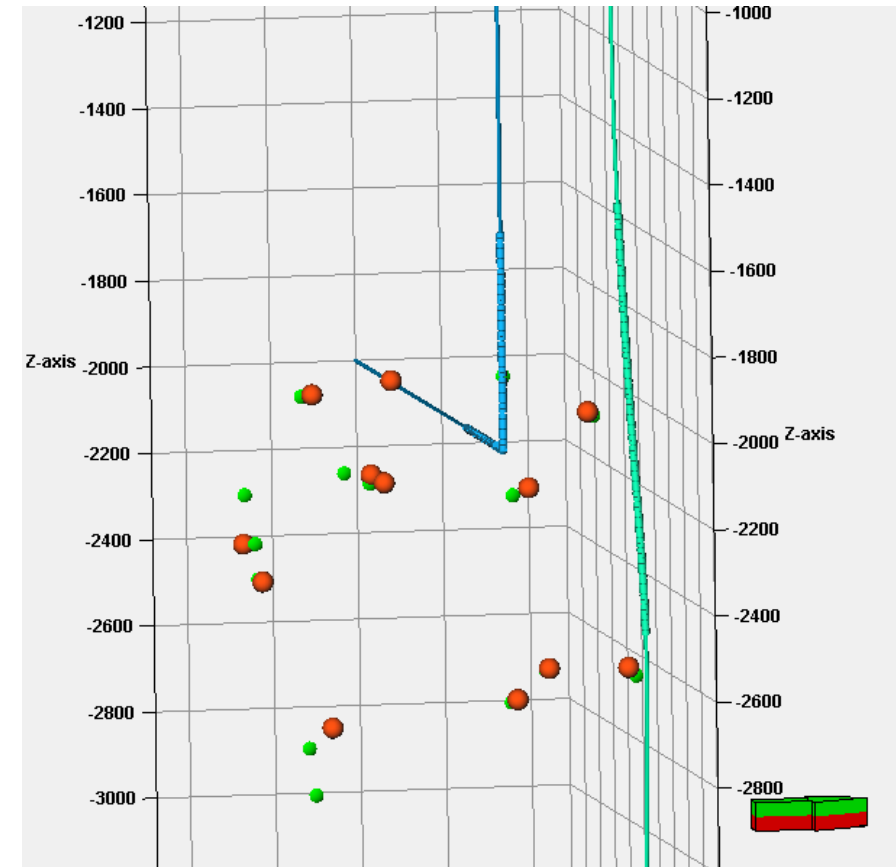

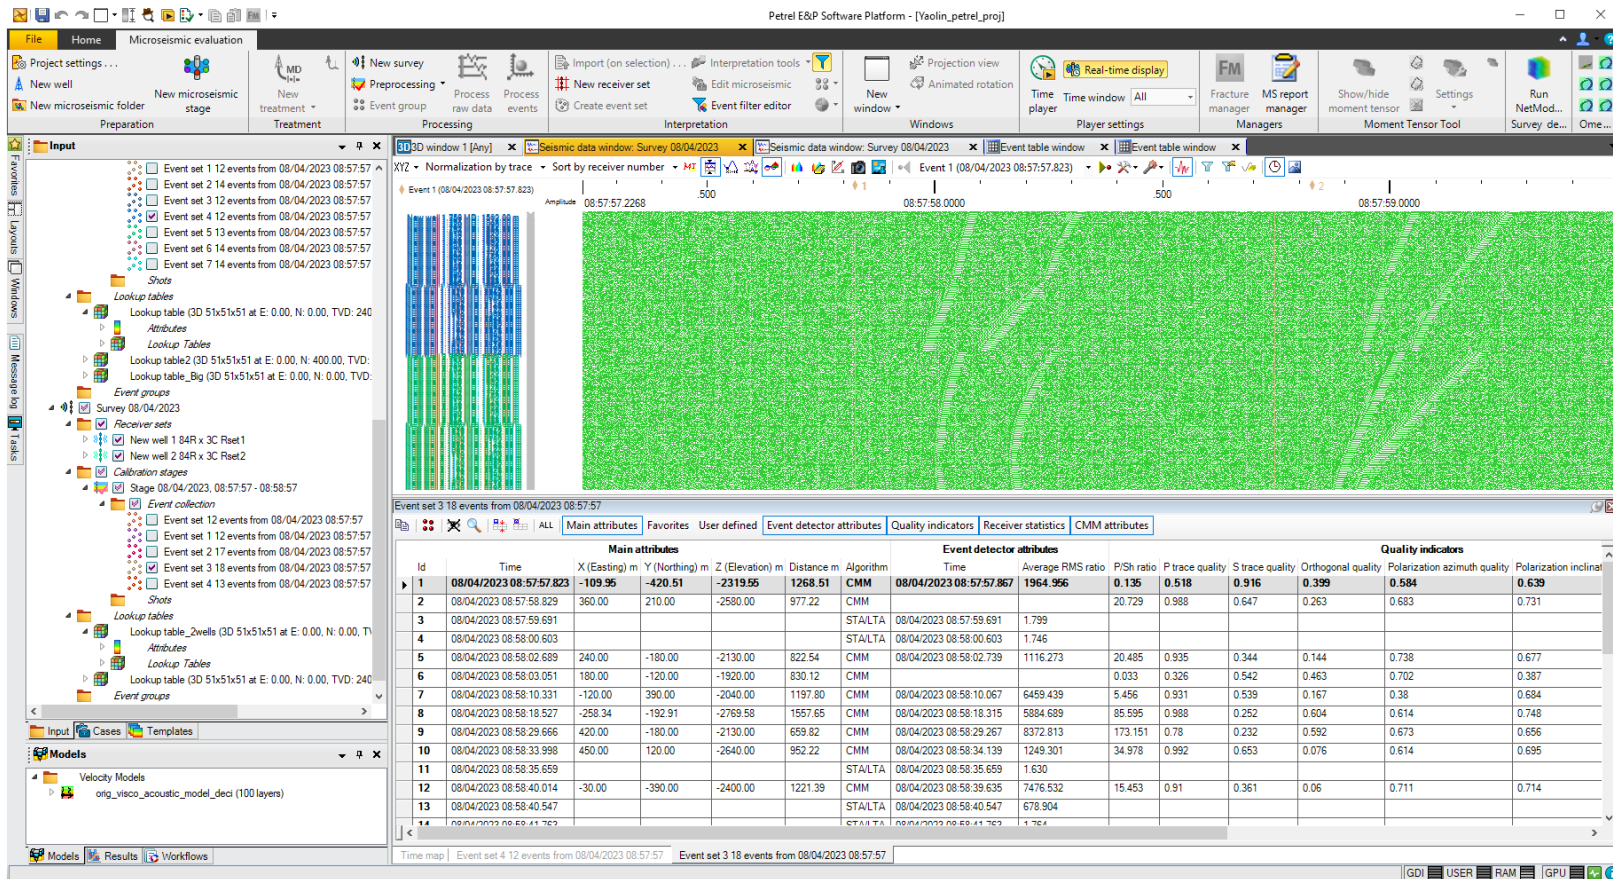

Units: meters

Cancel Continue

Testing with Petrel

Green: True Location
Red: Petrel location

Conclusions

- In this project, we implement a workflow for **real-time seismic data synthesis on virtual DAS arrays**, which is used to perform initial testing on the fluid injection monitoring platform
- This workflow focusing on generating synthetic seismicity and taking the use of **existing forward Modeler** to simulate waveforms of synthetic earthquakes
- It has been tested to simulate two days of data within 25 hours with no issue
- It has been tested with RT-ISA and Petrel for event location
- Future plans:
 - Testing the robustness of the workflow
 - Simulate data for longer duration
 - Limitations...

Thank you
